Annex 14

A/R Methodological Tool

"Estimation of GHG emissions related to fossil fuel combustion in A/R CDM project activities"

(Version 01)

I. SCOPE, APPLICABILITY AND PARAMETERS

Scope and applicability

This tool allows for estimating increase in GHG emissions¹ (both project and leakage emissions) related to fossil fuel combustion in A/R CDM project activities. The sources of emissions are: vehicles (mobile sources, such as trucks, tractors, etc.) and mechanical equipments (e.g., portable equipment such as chain saws and stationary equipment such as, water pumps) required by the A/R CDM project activity.

Parameters

This tool provides procedures to determine the following parameter:

Parameter	SI Unit	Description
$ET_{FC,y}$	t-CO ₂	CO_2 emissions from fossil fuel combustion during the year y

II. PROCEDURE²

$$ET_{FC,y} = \sum_{i=1}^{J} ET_{FC,j,y}$$
 (1)

Where:

 $ET_{FC,y}$: CO_2 emissions from fossil fuel combustion during the year y (t CO_2)

 $ET_{FC,j,y}$: CO₂ emission from fossil fuel combustion in vehicle/equipment type j during year y (tCO₂/yr)

j: Type of vehicle/equipment

J: Total number of types of vehicle/equipment used in the project activity

For estimation of $ET_{FC,j,y}$ the following two methods can be used:

- 1) Direct method
- 2) Indirect method

¹ For fossil fuel combustion in A/R project activities only CO2 emissions should be taken into account.

² Project proponents are reminded that the "Tool for testing significance of GHG emissions in A/R CDM project activities" could be applied to identify whether combustion emissions related to fossil fuel consumption are not significant for a particular CDM A/R project activity.

CDM - Executive Board

EB 33 Report Annex 14 Page 2

These can be used interchangeably, or simultaneously.

1) Direct method

Direct method assumes availability of data on the amount of fuel combusted. The method may be used in estimating vehicle/equipment emission in the project activity, when the vehicle/equipment is captive (i.e. controlled by the project participant) and the entire fuel consumptions can be monitored. The equation is as follows.

$$ET_{FC,j,y} = \sum_{i=1}^{I} FC_{i,j,y} * EF_{CO2\,i} * NCV_{i}$$
 (2)

Where:

 $ET_{FC,j,y}$: CO₂ emission from fossil fuel combustion in vehicle/equipment type j during year y (tCO₂/yr)

 $FC_{i,i,y}$: Quantity of fuel type i consumed in vehicle/equipment type j during year y (mass or volume unit

/ yr

 $EF_{CO2.i}$: CO₂ emission factor of the fuel type *i* combusted (tCO₂ / GJ)

 NCV_i : Net calorific value of fuel i (GJ/mass or volume unit)³

i: Fuel types combustedI: Total number of fuel types

2) Indirect method

This can be used when vehicle/equipment is not captive (i.e. when vehicle use is commissioned to third parties) and fuel consumption cannot be monitored by project, or in the case of ex ante estimation when key parameters are hypothetical.

For vehicles (mobile sources)⁴:

$$ET_{FC,j,y} = \sum_{i=1}^{I} n * MT_{j,y} / TL_{j,y} * AD_{j,y} * SECk_{j,i,y} * EF_{CO2,i} * NCV_{i}$$
(3a)

or

$$ET_{FC,j,y} = \sum_{i=1}^{I} NV_{j,y} * TD_{j,y} * SECk_{j,i,y} * EF_{CO2,i,} * NCV_{i}$$
(3b)

or

$$ET_{FC,j,y} = \sum_{i=1}^{I} MT_{j,y} *TD_{j,y} *SECkt_{j,i,y} *EF_{CO2,i} *NCV_{i}$$
(3c)

³ The conversion from volume units to mass units, whenever needed, shall be made by multiplying the volume (m³) by its density (kg/m³). Fuel density shall be obtained from verifiable local or national data.

⁴ For the estimation of GHG emissions related to transportation outside the project boundary only the distance up to the first point of commuting should be taken into consideration.

EB 33 Report Annex 14 Page 3

Where:

 $ET_{FC,i,y}$: CO₂ emission from fossil fuel combustion in vehicle/equipment type j during year y (tCO₂/yr)

n: Indicator of return load (dimensionless)⁵

 $MT_{i,y}$: Total mass transported by vehicle type j during year y (tonne)

 $TL_{i,y}$: Load capacity of vehicle type j during year y (tonne)

 $AD_{i,y}$ Average single-trip distance for vehicle type j during year y (km)

 $SECk_{j,i,y}$: Specific energy consumption of vehicle type j for fuel i during year y (quantity of fuel / km)

 EF_{CO2i} : CO₂ emission factor of the fuel type i combusted (t-CO₂ / GJ)

 NCV_i : Net calorific value of fuel i (GJ/mass or volume unit) $NV_{i,y}$: Number of vehicle type j during year y (dimensionless)

 $TD_{i,y}$: Total travel distance (including the return trip) for vehicle type j during year y (km)

 $SECkt_{i,i,y}$: Specific energy consumption of vehicle type j for fuel i during year y (quantity of fuel / tonne-

km)

i: Fuel types combustedI: Total number of fuel types

Where $MT_{j,y}$ cannot be obtained according to vehicle types, then $(MT_{j,y}/TL_{j,y})$ can be substituted by $(MT_y/TL_{av,y})$ where MT_y is the total mass transported, and $TL_{av,y}$ is the indicative load capacity of the fleet (i.e. the type of vehicle which has carried the most load).

For parameters $SECk_{j,i,y}$ in eq. 3b and $SECkt_{j,i,y}$ in eq. 3c, a reference figure can be used. Upon verification, DOE will check the parameters to ensure that the conditions which the parameters apply correspond to the situation of the project activity, or that a more conservative assumption is used.

Approach 3a is preferred to 3b, and 3b to 3c.

For equipment (stationary equipment):

$$ET_{FC,j,y} = \sum_{i=1}^{I} NE_{j,y} * TU_{j,y} * SECu_{j,i,y} * EF_{CO2.} * NCV_{ii}$$
(4)

Where:

 $ET_{FC,i,y}$: CO₂ emission from fossil fuel combustion in vehicle/equipment type j during year y (tCO₂/yr)

 $NE_{j,y}$: Number of equipment type j during year y (dimensionless)

 $TU_{j,y}$: Total use for equipment type j during year y (hours)

 $SECu_{i,i,y}$: Specific energy consumption of equipment type j for fuel i during year y (quantity of fuel / hour)

 EF_{CO2i} : CO₂ emission factor of the fuel type i combusted (t-CO₂ / GJ)

 NCV_i : Net calorific value of fuel i (GJ/mass or volume unit)

i: Fuel types combustedI: Total number of fuel types

For portable equipment (such as chainsaws), the equation above can only be used if verifiable data is available on the specific energy consumption. In this case, the product $TU_{j,y} *SECu_{j,i,y}$ can be replaced by, e.g. product of volume of harvested wood and fuel consumption per unit of volume of harvested wood.

 $^{^{5}}$ n = 1 when return load is full (with other commodity), n = 2 when return load is empty. If PPs cannot demonstrate that the return load is full then n=2.
