# CLEAN DEVELOPMENT MECHANISM PROJECT DESIGN DOCUMENT FORM (CDM-PDD) Version 03 - in effect as of: 28 July 2006

#### **CONTENTS**

- A. General description of <u>project activity</u>
- B. Application of a <u>baseline and monitoring methodology</u>
- C. Duration of the <u>project activity</u> / <u>crediting period</u>
- D. Environmental impacts
- E. <u>Stakeholders'</u> comments

#### **Annexes**

- Annex 1: Contact information on participants in the project activity
- Annex 2: Information regarding public funding
- Annex 3: Baseline information
- Annex 4: Monitoring plan

CDM - Executive Board

page 2

# SECTION A. General description of project activity

# A.1. Title of the <u>project activity</u>:

São Fernando Biomass Cogeneration Project

Current version: 04 Date: 21/09/2010

# A.2. Description of the <u>project activity</u>:

The São Fernando Biomass Cogeneration Project foresees the operation of a new sugarcane bagasse fired cogeneration unit at the sugar and ethanol mill Usina São Fernando, located in the municipality of Dourados, in the Brazilian state of Mato Grosso do Sul.

The project developer is São Fernando Açúcar e Álcool Ltda, belonging to Grupo Bertin (Bertin Group) a Brazilian holding company that includes several different activities in its portfolio, such as energy generation, biodiesel, food companies, cosmetics, agro industry or infrastructures.

The cogeneration unit is expected to be built during the next five years and will achieve a top installed capacity generation of 128 MW, through the installation of three turbo-generators and two boilers, as follows:

| PERIOD | SUGARCANE HARVEST AREA | TOTAL INSTALLED CAPACITY |
|--------|------------------------|--------------------------|
| 2009   | 21,600 Ha              | 1 * 48 MW                |
| 2010   | 41,350 Ha              | 1 * 48 MW                |
| 2011   | 46,350 Ha              | 2 * 48 MW                |
| 2012   | 50,150 Ha              | 2 * 48 MW + 1 * 32 MW    |
| 2013   | 50 150 Ha              | 2 * 48 MW + 1 * 32 MW    |

The turbines and generators installed for power generation have a top capacity of 128 MW. However, due to the absence of more bagasse available for firing and the limitations on the capacity of the boilers for heat generation, the project plant is never expected to reach its top installed capacity of generation.

When the project activity finishes its last stage of construction and the quantity of bagasse available for stoking the boilers reaches its highest value, the cogeneration unit will only be able to achieve a maximum power capacity of 114 MW.

The main purpose of the project activity is to increase the quantity of power generation using the sugarcane bagasse generated and to export the resulting extra power to the Brazilian grid, the National Interconnected System of Brazil, *Sistema Interligado Nacional do Brasil (SIN)*.

The project activity intends to make efficient use of resources while minimizing the impact on the environment, in order to supply Brazil's rising demand of energy and to improve the supply of electricity, while contributing to the environmental, social and economic sustainability of the country by increasing renewable energy's share of the whole Brazilian power consumption.

**CDM – Executive Board** 

page 3

Grupo Bertin has always been very concerned about the emissions related with its industrial activities. They have already developed several GHG emission reduction projects, such as reforestation, construction of a recycling plant for all the companies of the holding or wastewater treatments in the slaughterhouses and tanneries. Actually, Bertin was one of the first companies in Brazil which resorted to the Clean Development Mechanism, through the presentation in 2005 of two fuel switching projects at slaughterhouses and tanneries. A small hydro power plant project was also suggested under the CDM activity in 2007.

São Fernando Açúcar e Álcool, as a part of Grupo Bertin, pretends to help in the research of the sustainable development by promoting activities that agree with the social and environmental responsibilities of the company. The São Fernando cogeneration plant is one of these activities.

#### **Environmental benefits**

The main purpose of the São Fernando Cogeneration Project is to contribute to sustainable development in Brazil through the effective utilization of biomass residues available for power and heat generation. Therefore, the project helps with the climate change mitigation by generating clean power and by reducing the fossil fuel based power generation of the Brazilian grid, the National Interconnected System of Brazil.

The company has developed the *Programa Básico Ambiental* (Environmental Basic Program) which involves 14 different programs addressed to the population of Mato Grosso do Sul and is carried out in order to improve the social and environmental situation of the region. These programs include the following items:

- Vegetation Monitoring
- Fauna monitoring
- Monitoring of water quality
- Monitoring of air quality
- Land monitoring
- Solid residues management
- Land erosion processes control
- Noise monitoring
- Degraded areas recuperation
- Regulation of legal reserves
- Workplace risks prevention
- Environmental education
- Social communication
- Risks management and emergency actions

#### **Social benefits**

The project will create employment in the region for the installation, operation and maintenance of the sugarcane plant. The whole construction (sugarcane plant and cogeneration unit) will generate 1.100 direct and 4.400 indirect employments in its first year. The job creation will achieve 1.800 direct and 7.200 indirect employments after 5 year operation, when the cogeneration unit gets its top power generation. Regarding to professional qualifications, the São Fernando project pays special attention and effort to local community education, believing that this way contribute to the increase of their own income. Apart of the employments due to the straight construction and operation of the plant, there will also be job generation indirectly related to the project activity, such as research and development (R & D), production and maintenance of equipment.

The project will also help with the distribution of income and will increase the municipal tax collection, which means an indirect benefit for the citizens of the region.

CDM - Executive Board

page 4

#### **Economical benefits**

The implementation of the project activity creates a new option to generate revenue through the sale of electricity and CERs, which ensures a greater financial sustainability. The project also promotes a better interaction between the sugarcane and the energy sectors.

The sugarcane based industry is one of the most important economic sectors in Brazil. The most of the sugar mills are located in the Central and South regions of the country, especially in the state of São Paulo. Only around the 7% of the sugarcane plants in Brazil are located in the state of Mato Grosso do Sul. Thus, São Fernando cogeneration project will help with the economic development and at the same time will contribute to the energy needs of the region.

As it is a locally sourced fuel, bagasse will increase the reliability of electricity supply by diversifying sources and by reducing fossil fuel dependence.

The São Fernando cogeneration unit will increase the national grid stability and reliability as well decreasing the needs for costly investments in grid upgrading in the state of Mato Grosso do Sul.

#### A.3. Project participants:

| Name of Party involved (*)<br>((host) indicates a host Party) | Private and/or public entity(ies) project participants (*) (as applicable) | Kindly indicate if the Party involved wishes to be considered as project participant (Yes/No) |
|---|--|---|
| Don-11 (1-1-4)  | São Fernando Açúcar e Álcool<br>Ltda. (Private Entity)                     | No  |
| Brazil (host)   | Zeroemissions do Brasil Ltda.<br>(Private Entity)                          | No  |

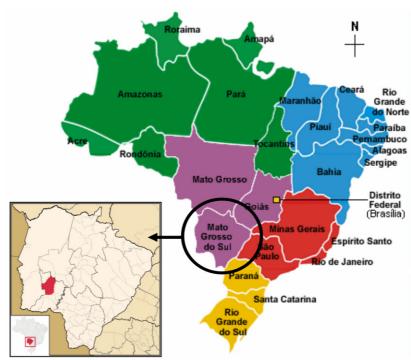

<sup>(\*)</sup> In accordance with the CDM modalities and procedures, at the time of making the CDM-PDD public at the stage of validation, a Party involved may or may not have provided its approval. At the time of requesting registration, the approval by the Party (ies) involved is required.

#### A.4. Technical description of the <u>project activity</u>:

#### A.4.1. Location of the project activity:

São Fernando Cogeneration Project is located in the municipality of Dourados in the state of Mato Grosso do Sul.

page 5

Location of São Fernando Cogeneration Project in the State of Mato Grosso do Sul, Brazil

# A.4.1.1. <u>Host Party</u>(ies):

Brazil.

# A.4.1.2. Region/State/Province etc.:

Mato Grosso do Sul.

#### A.4.1.3. City/Town/Community etc.:

Dourados.

# A.4.1.4. Details of physical location, including information allowing the unique identification of this <u>project activity</u> (maximum one page):

The exact address of the plant is km 8, MS-379 road, located in the municipality of Dourados (Paraná Hydrographical Basin and Dourados river hydrographical basin).

The exact location of the project is defined using the following coordinates, given by the technical data that the Brazilian National Electricity Agency (ANEEL) considered as the location of the cogeneration unit of São Fernando:

Latitude: 22° 18′ 53" S | Longitude: 54° 55′ 57" W

UNFCCC

CDM - Executive Board

#### A.4.2. Category(ies) of project activity:

- Type: Energy and Power.
- Sectoral Scope: 1 Energy industries (renewable / non-renewable sources).
- Category: Renewable electricity generation for a grid (energy generation, supply, transmission and distribution).

#### A.4.3. Technology to be employed by the <u>project activity</u>:

The predominant technology all around the world for generating megawatt (MW) levels of electricity from biomass is the steam-Rankine cycle. The proposed technology of this project activity will use biomass as a fuel in the high pressure boiler and high pressure steam will be generated and expanded in the back pressure turbine, generating power and steam.

The Rankine Cycle is a very common and mature technology. It involves boiling pressurized water and steam generation, expansion of the generated steam in backpressure turbines with power generation, and condensation of water for recycling.

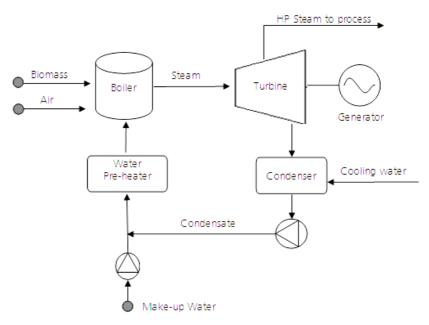

Most steam cycle plants are located at industrial sites, where the waste heat from the steam turbine is recovered and used for meeting industrial-process heat needs. Such Combined Heat and Power (CHP), or cogeneration, systems provide greater levels of energy services per unit of biomass consumed than systems that generate only power.

Steam turbines are designed as either "back-pressure" or "condensing" turbines. CHP applications typically employ back-pressure turbines, wherein steam expands to a pressure that is still substantially above ambient pressure. It leaves the turbine still as a vapour and is sent to satisfy industrial heating needs, where it condenses back to water. It is then partially or fully returned to the boiler. Alternatively, if process steam demands can be met using only a portion of the available steam, a Condensing Extraction Steam Turbine (CEST) might be used. This design includes the capability for some steam to be extracted at one or more points along the expansion path for meeting process needs (see figure below).

Steam that is not extracted continues to expand to sub-atmospheric pressures, thereby increasing the amount of electricity generated per unit of steam compared to the back-pressure turbine. The non-extracted steam is converted back to liquid water in a condenser that utilizes ambient air and/or a cold water source as the coolant.

page 7

Schematic diagram of a biomass-fired steam Rankine cycle for cogeneration

More than the technology, the real reasons of the success of cogeneration are some appealing economic, operational and environmental advantages. Cogeneration systems offer several potential industry and benefits for the user. Some key financial, operational and environmental advantages and benefits of cogeneration have been identified and are summarized in the following table:

| Advantages & Benefits   |   |                            |  |  |
|---|---|----------------------------|--|--|
| Financial   | Operational   | Environmental              |  |  |
| Reduce primary energy cost by up to 30%                             | Improve the security of electrical supply                       | Reduce fossil fuel usage   |  |  |
| Reduce energy expenses by up to 20%                                 | Reduce or eliminate utility power purchases                     | Increase energy efficiency |  |  |
| Stabilize the risks associated with rapidly rising energy prices    | Improve the security of heat supply                             | Reduce GHG emissions       |  |  |
| Provide potential additional revenues through sales of excess power | Eliminate the need for expensive electrical connection upgrades |                            |  |  |
|   | Provide electricity, heat and cooling simultaneously            |                            |  |  |

Advantages and benefits of cogeneration systems

The project activity implements the necessary equipments for cogeneration during three stages, and each one of them increases the power generation. Based in the above explanation, the list of the equipments that will be installed within the project activity is described below:

**CDM** – Executive Board

page 8

# • Stage I (2009-2010)

Installation of the first boiler, turbine and generator. The plant will reach a total generation capacity of 48 MW. The characteristics of the equipments are the following:

|        | Characteristic    | Description  | Unit |
|--------|-------------------|--------------|------|
|        | Manufacture       | HPB/Sermatec | 1    |
|        | Brand             | HPB          | -    |
|        | Model             | VS-500/1     | -    |
| Boiler | Steam             | 250          | t/h  |
| Doller | Steam Temperature | 540          | °C   |
|        | Water Temperature | 120          | °C   |
|        | Pressure          | 100          | Bar  |
|        | Fuel              | Bagasse      | -    |
|        | Efficiency        | 87           | %    |

|         | Characteristic        | Description | Unit   |

page 10

#### • Stage III (2012-2013)

Installation of the last turbine and generator. The plant will achieve a top installed capacity of 128 MW. However, as explained before, according to the engineering studies carried out prior to the project implementation, with the bagasse available for firing and the limitations on the capacity of the boilers for vapor generation, the project plant will not be able to generate more than 114 MW.

Technical characteristics of the new equipments installed in the stage III, as follows:

|         | Characteristic        | Description | Unit   |
|---------|-----------------------|-------------|--------|
|         | Manufacture           | TGM         | -      |
|         | Brand                 | TGM         | -      |
|         | Model                 | BT 40       | -      |
| Turbine | Capacity MW           | 40          | MW     |
|         | Capacity KVA          | 47,200      | kVA    |
|         | r.p.m.                | 6,800       | r.p.m. |
|         | Pressure              | 16          | Bar    |
|         | Admission Temperature | 276.67/530  | °C/F°  |

|           | Characteristic | Description         | Unit   |
|-----------|----------------|---------------------|--------|
|           | Manufacture    | WEG                 | =      |
|           | Brand          | WEG                 | -      |
|           | Model          | SPW 1,250           | -      |
| Company   | Voltage        | 13.8 kV             | kV     |
| Generator | Frequency      | 60 Hz               | Hz     |
|           | r.p.m.         | 1,800               | r.p.m. |
|           | Capacity MW    | 32                  | MW     |
|           | Capacity KVA   | 40,000              | KVA    |
|           | Refrigeration  | Air/water exchanger | -      |

|            | Characteristic | Description       | Unit |
|------------|----------------|-------------------|------|
| Substation | Capacity       | 4 * 30,000/37,500 | kVA  |
|            | Voltage        | 138               | kV   |

|             | Characteristic | Description   | Unit |
|-------------|----------------|---------------|------|
| Transformer | Capacity       | 30,000/37,500 | kVA  |
|             | Voltage        | 138           | kV   |

The evolution of the installed capacity during the first five years of the project activity, until the plant reaches the top generation, is detailed in the table below:

| Year | Total installed capacity (MW) |
|------|-------------------------------|
| 2009 | 48                            |
| 2010 | 48                            |
| 2011 | 96                            |
| 2012 | 128                           |
| 2013 | 128                           |

**CDM - Executive Board** 

page 11

#### A.4.4. Estimated amount of emission reductions over the chosen crediting period:

The chosen crediting period for the project activity is the renewable crediting period of 7 years. The estimated amount of emission reductions appears in the following table. The project will consider the expost method for calculating the emission factor. In other words, the project participants will calculate the project emission reductions using the Brazilian DNA provided data (operating margin emission factor & build margin emission factor) when the verification is completed. The emission factor is calculated by the Brazilian DNA by using the "Tool to calculate the emission factor for an electricity system", version 02.

| Years   | Annual estimation of emission reductions (tCO <sub>2</sub> ) |
|---|--|
| 06/2011 – 12/2011   | 47,110   |

# A.4.5. Public funding of the project activity:

There is no public funding of Annex I parties involved in the project activity.

UNFCCC

DM – Executive Board

page 12

## SECTION B. Application of a baseline and monitoring methodology

#### B.1. Title and reference of the approved baseline and monitoring methodology applied to the project activity:

Baseline methodology approved and consolidated ACM0006 - version 10: "Consolidated baseline methodology for grid-connected electricity generation from biomass residues in power and heat plants".

The application methodology draws upon the following tools and methodologies:

- ACM0002: "Consolidated baseline methodology for grid-connected electricity generation from renewable sources"
- "Combined tool to identify the baseline scenario and demonstrate additionality"; version 02.2
- "Tool to determine methane emissions avoided from disposal of waste at a solid waste disposal
- "Tool to calculate project or leakage CO2 emissions from fossil fuel combustion"; version 02
- "Tool to calculate baseline, project and/or leakage emissions from electricity consumption"; version 01
- "Tool to calculate the emission factor for an electricity system"; version 02.

#### **B.2.** Justification of the choice of the methodology and why it is applicable to the project activity:

The project activity intends to install a new power plant fired with sugarcane bagasse, in order to generate power in a location where no energy is currently generated. Therefore, according to methodology ACM0006, this is a "Greenfield Power Project".

The project complies with the methodology applicability conditions:

No other biomass types than biomass residues, as defined in the Methodology ACM0006 / version 10, page 2, are used in the project plant and these biomass residues are the predominant *fuel used in the project plant (some fossil fuels may be co-fired);* 

The unique fuel used in the project plant is a biomass residue consisting of sugarcane bagasse. The bagasse used in the São Fernando Cogeneration Plant comes from the production of alcohol and sugar carried out in the same facility where the project is located. Therefore, the project only uses biomass residues as input.

For projects that use biomass residues from a production process (e.g. production of sugar or wood panel boards), the implementation of the project shall not result in an increase of the processing capacity of raw input (e.g. sugar, rice, logs, etc.) or in other substantial changes (e.g. product change) in this process;

**CDM - Executive Board** 

page 13

The sugar and ethanol plant will not increase their current sugarcane processing capacity because of the CDM project, but rather due to the recent increase of the production and the demand of sugar and ethanol in the country. The supply of ethanol in the Brazilian market is not sufficient to meet the rising demand caused by the introduction of flex-fuel automobiles that run on gasoline, ethanol or a blend of both.

Moreover, according to the National Supply Company (CONAB, Companhia Nacional de Abastecimento, a public and reliable font belonging to the Brazilian Ministry of Agriculture), it is expected sugarcane cultivated in the South regions of Brazil for December 2008 harvest season to increase compared to the previous cycle. In words of CONAB, sugarcane production in the Central-South region in 2008 will reach the 502 million tones, which means an increase of 15.34% compared with 2007<sup>1</sup>.

The biomass residues used by the project facility should not be stored for more than a year.

The percentage of the bagasse used per year in the cogeneration plant is almost the total production of bagasse per year in the sugar and alcohol production line. Only around 7% of the total amount of bagasse generated during the harvest season is stored for restarting the production in the next harvest. In any case, this bagasse is stored from the end of the harvest season, in November, until the beginning of the following harvest season, in April, which means less than a year.

No significant energy quantities, except from transportation or mechanical treatment of the biomass residues, are required to prepare the biomass residues for fuel combustion, i.e. projects that process the biomass residues prior to combustion (e.g. esterification of waste oils).

The biomass residue for fuel combustion, the bagasse, is the product of a mechanical operation after sugarcane's reception and there is no transportation involved of bagasse in this project.

### **B.3.** Description of the sources and gases included in the project boundary:

|          | Source                      | Gas              |          | Justification / Explanation  |
|----------|-----------------------------|------------------|----------|--|
|          | Cuid alantuinita            | $CO_2$           | Included | Main emission source.  |

The following flow diagram defines the project boundaries:

**CDM - Executive Board** 

page 15

The cogeneration unit of the project activity consists of the following equipments (which technical characteristics were described in the section A.4.3 of the PDD):

- Two bagasse fired boilers.
- Three turbines.
- Three generators.

# **B.4.** Description of how the baseline scenario is identified and description of the identified baseline scenario:

The project activity consists of the installation of a new sugarcane bagasse fired cogeneration unit in a place where no power is currently being generated. The cogeneration plant is located in the new sugarcane mill of São Fernando and will fire the bagasse resulting from the processing of the sugarcane for power and heat generation. The project plant will achieve a top capacity of generation of 114 MW through the installation of new high efficient cogeneration equipments, and the energy generated will be used for meeting the needs of the São Fernando's industrial process. The power surplus will be injected to the national grid.

In absence of the project activity, project participants would have also built a new cogeneration unit (the reference plant) at the same site, fired with the same type and quantity of bagasse, but with an efficiency of electricity generation which is common practice in the Brazilian sugarcane industry. This means that, as it is common practice in the sector, the reference plant would have lower efficiency than the project activity and it would generate power only for meeting the requirements of the sugarcane processing plant. Therefore, in this case there will not be any power generation surplus for exporting to the grid.

According to the chosen methodology, ACM0006 version 10, the identification of the baseline scenario is determined by the analysis of the following alternatives:

- How power demand would be covered in the absence of the CDM project activity.
- What would happen to the biomass residues in the absence of the project activity.
- In case of cogeneration projects: how the heat would be generated in the absence of the project activity.

For **power** generation, the following scenarios have been considered as plausible alternatives:

| Scenario | Description  | Comments   | Plausible |
|----------|--|--|-----------|
| P1       | The proposed project activity not undertaken as a CDM project activity.  | This could be considered as a plausible scenario. However, as it will be shown afterwards in the investment analysis, the proposed project activity without the CDM benefits is not financially attractive for project developers. Therefore, this is not a feasible scenario. | No        |
| P2       | The continuation of power generation in an existing biomass residue fired power and heat plant at the project site, in the same configuration, without retrofitting and fired with the same type of biomass residues as (co-) fired in the project activity. | This is a Greenfield Power Project.  | No        |

page 16

| Р3 | The generation of power in an existing captive power and heat plant, using only fossil fuels.   | This is a Greenfield Project Activity.   | No  |
|----|---|--|-----|
| P4 | The generation of power in the grid.  | In absence of the project activity, a reference plant would be built with a less efficient technology for power generation. The reference plant would fire the same type and quantity of biomass residues as the project plant, but with a lower efficiency of power generation (the one that is common practice for sugarcane bagasse fired power plants in the state of Mato Grosso do Sul). | Yes |
|    |   | Therefore, the difference of power generation between the project plant and the reference plant would be taken from the grid.  |     |
| P5 | The installation of a new biomass residue fired power and heat plant, fired with the same type and with the same annual amount of biomass residues as the project activity, but with a lower efficiency of electricity generation (e.g. an efficiency that is common practice in the relevant industry sector) than the project plant and therefore with a lower power output than in the project case.             | In absence of the project activity, a reference plant would be built with a less efficient technology for power generation. The reference plant would fire the same type and quantity of biomass residues as the project plant, but with a lower efficiency of power generation (the one that is common practice for sugarcane bagasse fired power plants in the state of Mato Grosso do Sul). | Yes |
| P6 | The installation of a new biomass residue fired power and heat plant that is fired with the same type but with a higher annual amount of biomass residues as the project activity and that has a lower efficiency of electricity generation (e.g. an efficiency that is common practice in the relevant industry sector) than the project activity. Therefore, the power output is the same as in the project case. | In absence of the project activity, a reference plant fired with the same type and quantity of biomass residue as in the project plant would be built.  The amount of biomass residues available in the project activity for cogeneration is the same as in the baseline scenario, which is the quantity of bagasse produced by the sugar and ethanol production process.                      | No  |
| P7 | The retrofitting of an existing biomass residue fired power and heat plant, fired with the same type and with the same annual amount of biomass residues as the project activity, but with a lower efficiency of electricity generation (e.g. an efficiency that is common practice in the relevant industry sector) than the project plant and therefore with a lower power output than in the project case.       | This is a Greenfield Power Project.  | No  |
| P8 | The retrofitting of an existing biomass residue fired power and heat plant that is fired with the same type but with a higher annual amount of biomass residues as the project activity and that has a lower efficiency of electricity generation (e.g. an  | This is a Greenfield Power Project.  | No  |

page 17

|     | efficiency that is common practice in the relevant industry sector) than the project activity.  |  |    |
|-----|---|--|----|
| P9  | The installation of a new fossil fuel fired captive power and heat plant at the project site.   | The objective of the project developers is to build a new grid connected cogeneration plant, in order to meet the heat and power needs of their production process and to obtain extra revenues through the sale of the power surplus to the grid.  Besides, a fossil fuel fired plant would lead to higher emissions. In this case, the project activity could not receive the benefits of the CDM, which are necessary to ensure the | No |
| P10 | The installation of a new single- (using only biomass residues) or co-fired (using a mix of biomass residues and fossil fuels) cogeneration plant with the same rated power capacity as the project activity power and heat plant, but that is fired with a different type and/or quantity of fuels (biomass residues and/or fossil fuels). The annual amount of biomass residue used in the baseline scenario is lower than that used in the project activity. | financial feasibility of the project.  The type and quantity of biomass residues in the baseline is the same as in the project activity.  The cogeneration plant only fires biomass residues proceeding from the sugar and ethanol production process associated to the project activity.  | No |
| P11 | The generation of power in an existing fossil fuel fired cogeneration plant co-fired with biomass residues, at the project site.  | There is not any cogeneration plant currently existing at the project site.  | No |

For the use of **biomass**, the following scenarios are plausible alternatives:

| Scenario | Description                                  | Comments                                       | Plausible |

|  | plant.                                       |  |

For **heat** generation, the following scenarios have been considered as plausible alternatives:

| Scenario | Description   | Comments   | Plausible |
|----------|---|--|-----------|
| Н1       | The proposed project activity not undertaken as a CDM project activity.   | This may be considered as plausible scenario. However, as it will be shown afterwards in the investment analysis, the proposed project activity without the CDM benefits is not financially attractive for project developers. Therefore, this is not a feasible scenario.   | No        |
| Н2       | The proposed project activity (installation of a power and heat plant), fired with the same type of biomass residues but with a different efficiency of heat generation (e.g. an efficiency that is common practice in the relevant industry sector).  In absence of the project activity, the same heat would be generated by the reference plant, which would use the same type and quantity of biomass residues.  In the case of the reference plant, the efficiency of heat generation would be the one that is common practice in sugarcane bagasse fired plants of the state of Mato Grosso do Sul. |  | Yes       |
| Н3       | The generation of heat in an existing captive power and heat plant, using only fossil fuels.  | This is a Greenfield Power Project.  | No        |
| Н4       | The generation of heat in boilers using the same type of biomass residues.  | In absence of the project activity, the same heat would be generated by the reference plant, which would use the same type and quantity of biomass residues.  Since the main objective of project developers is to generate power and heat in order to meet the energy needs of their sugar and ethanol production process, using the bagasse purchased only for heat generation in boilers is not an attractive alternative for them. | No        |
| Н5       | The continuation of heat generation in an existing biomass residue fired power and heat plant at the project site, in the same configuration, without retrofitting and fired with the same type of biomass residues as in the project activity.   | This is a Greenfield Power Project.  | No        |
| Н6       | The generation of heat in boilers using fossil fuels.   | Since the same quantity of sugarcane bagasse fired in the project activity for power and heat generation would be available in the baseline scenario, in absence of the project activity, the same heat would be generated by the reference plant, using the same type and quantity of biomass   | No        |

#### CDM - Executive Board

page 20

|     |   | residues.  |    |
|-----|---|--|----|
|     |   | residues.  |    |
|     |   | Since the main objective of project developers is to generate power and heat in order to meet the energy needs of their sugar and ethanol production process, using the bagasse purchased only for heat generation in boilers is not an attractive alternative for them.   |    |
| Н7  | The use of heat from external sources, such as district heat.   | There is no heat generation from external sources at the project site.   | No |
| Н8  | Other heat generation technologies (e.g. heat pumps or solar energy).   | There are no other heat generation technologies currently being adopted by the sector in Brazil.   | No |
| Н9  | The installation of a new single- (using only biomass residues) or co-fired (using a mix of biomass residues and fossil fuels) power and heat plant with the same rated power capacity as the project activity power and heat plant, but that is fired with a different type and/or quantity of fuels (biomass residues and/or fossil fuels). The annual amount of biomass residue used in the baseline scenario is lower than that used in the project activity. | The objective of the project developers is to build a cogeneration plant fired only with the sugarcane bagasse available from the sugar and ethanol production process associated to the project activity. Using any other type of biomass residues or fossil fuels is not a convenient option for project developers. | No |
| H10 | The generation of power in an existing  | There is not any cogeneration plant currently  | No |
|     | fossil fuel fired cogeneration plant co-fired   | existing at the project site.  |    |
|     | with biomass residues, at the project site.   |  |    |

Thus, the available alternatives for the baseline scenario are:

• For power generation: P1 and P4 in conjunction with P5.

• For the use of biomass residues: B4.

• For heat generation: H1 and H2.

Hence, according to the methodology, two different alternatives are available scenarios:

- The project activity not undertaken as a CDM project (P1, H1 and B4)
- The scenario #4 of the methodology ACM0006, version 10, corresponding to the following description (P4, P5, H2 and B4):

The project activity involves the installation of a **new biomass residue fired power and heat plant** at a site where no power was generated prior to the implementation of the project activity. In the absence of the project activity, a new biomass residue fired power and heat plant (in the following referred to as **"reference plant"**) would be installed instead of the project activity at the same site and with the same thermal firing capacity but with a lower efficiency of electricity generation as the project plant (e.g. by using a low-pressure boiler instead of a high-pressure boiler). The same type and quantity of biomass residues as in the project plant would be used in the reference plant (B4). Consequently, the power generated by the project plant would in the absence of the project activity be generated (a) in the

**CDM - Executive Board** 

page 21

reference plant (P5) and – since power generation is larger in the project plant than in the reference plant – (b) partly in power plants in the grid (P4). The heat generated by the project plant would in the absence of the project activity be generated in the reference plant (H2).

This paragraph completely agrees with the description of the project activity, so the case #4 has been chosen as the appropriated alternative of the baseline scenario.

According to the methodology ACM0006, version 10, Project Participants shall identify the most plausible baseline scenario and demonstrate additionality using the latest approved version of the "Combined tool to identify the baseline scenario and demonstrate additionality", which is version 02.2. The application of the Combined Tool has been developed in section B.5.

B.5. Description of how the anthropogenic emissions of GHG by sources are reduced below those that would have occurred in the absence of the registered CDM project activity (assessment and demonstration of additionality):

#### Awareness of the CDM process

Since the very beginning of the project activity, project developers knew the possibility of including the CDM benefits as a part of the São Fernando cogeneration project and they took it into account for the project economical feasibility study. A clear evidence of this early consideration is the reference to the CDM mechanism included in the minutes of the Grupo Bertin's Board meeting on September 2007, where it is agreed that the project developers would look for consultancy companies for carrying out the CDM project development.

Grupo Bertin created a CDM Department in order to study the different possibilities of including their investments into the Clean Development Mechanism. This department already studied the CDM consideration of the São Fernando project at the beginning of 2007. On the minutes of the Bertin's CDM Department meeting on January 2007 they discussed the different possibilities for CDM projects in the investments of the company. São Fernando project is one of these possibilities.

Grupo Bertin also has the copy of different offers from Zeroemissions Technologies (PDD consultant) in which the company offers its consultancy services for developing the CDM project for São Fernando Cogeneration Plant. These three offers are dated respectively on October 2007, March 2008 and August 2008.

The evidences about the prior consideration of the CDM project will be shown to the DOE during the validation.

Apart from this, as explained at the beginning of the PDD, Grupo Bertin has already developed two CDM projects in 2005, referred to fuel switching in slaughterhouses and tanneries and one more project in 2007 about clean energy generation in a small hydro power plant. This evidence helps to demonstrate that project developers had prior consideration of the CDM for the São Fernando cogeneration project and for any other project of this kind that they could carry out.

CDM – Executive Board

page 22

#### Reduction of GHG are reduced below those that would have occurred in the absence of the Project

As it will be discussed later, one of the alternative scenarios to the project activity is the construction of a new cogeneration plant with less efficient equipments. This plant, with the same installed capacity, would fire the same type and quantity of biomass residues as in the project plant, but with a lower power generation. In this case, the difference between the power generated by the project plant and the power generated by the less efficient plant would be generated by other facilities that are currently connected to the grid and are not under the control of the project participants.

According to the methodology ACM0006, version 10, Project Participants shall identify the most plausible baseline scenario and demonstrate additionality using the latest approved version of the "Combined tool to identify the baseline scenario and demonstrate additionality", which is version 02.2. According to this tool (hereafter the Combined Tool), participants shall apply the following four steps:

STEP 1. Identification of alternative scenarios

STEP 2. Barrier analysis

STEP 3. Investment analysis (if applicable)

STEP 4. Common practice analysis

# STEP 1: Identification of alternative scenarios

#### Sub-step 1a: Define alternative scenarios to the proposed CDM project activity

The following alternative scenarios are available alternatives to the project activity (as it has been demonstrated in section B.4):

- The project activity not undertaken as a CDM project activity.
- The construction of a cogeneration plant, fired with the same type and quantity of biomass residues, but with a power generation efficiency which is common practice in the sector. This means the installation of less efficient boilers and turbines. The plant would not have enough capacity for generating energy in order to cover the power needs of the industrial process and should import a part of energy from the grid. As said before, in this case the difference between the power generated by the project plant and the less efficient plant would be generated by other facilities that are connected to the grid and are not under control of the project participants.

#### Sub-step 1b: Consistency with mandatory laws and regulations

Both identified alternative scenarios are in compliance with all mandatory laws and regulations currently applicable in Brazil.

Considering the identified alternative scenarios, the consistency with laws and regulations has been analyzed on the basis of the exigencies and requirements established by the Secretary of Environment of the State of Mato Grosso do Sul (SEMAC) and the National Electricity Agency (ANEEL).

#### **CDM** – Executive Board

page 23

The Secretary of Environment of the State of Mato Grosso do Sul (SEMAC) is responsible for analyzing any possible environmental impact due to the project activity normal development. The licenses required by the Brazilian environmental regulation are:

- The preliminary license (Licença Prévia, LP).
- The construction license (*Licença de Instalação*, *LI*).
- The operating license (Licença de Operação, LO).

São Fernando has already all the required licenses, as detailed below:

- Preliminary licenses number 20/2009 (for the transmission line) and 27/2009 (for the substation).
- Construction license number 129/2008.
- Operating licenses protocol number 256/2009 (for the cogeneration unit), 285/2009 (for the substation) and 288/2009 (for the transmission line).

The cogeneration plant also has its authorization and registration on the National Agency of Electrical Energy (ANEEL) to operate as an independent power producer. Therefore, the project activity obeys all the mandatory laws and regulations of the state of Mato Grosso do Sul.

As detailed before, the two available scenarios for the project activity are the following:

1. The project activity not undertaken as a CDM project.

Since the project participants have already obtained all the necessary licences for the construction and operation of the project plant, the construction of the same project plant, with the same characteristics but without considering the CDM revenues, would also be consistent with the laws and regulations currently applicable in Brazil.

2. The construction of a new cogeneration plant less efficient than the project plant, according to scenario #4 of the methodology ACM0006.

In this case, a new biomass residue fired power plant (the reference plant) would be installed instead of the project activity at the same site and with the same thermal firing capacity but with lower efficiency of electricity generation than the project plant. The same type and quantity of biomass residues as in the project plant would be used in the reference plant.

Therefore, since the reference plant would be located at the same site as the project plant, with the same characteristics and a power generation efficiency that is common practice in the state of Mato Grosso do Sul, no mandatory laws or regulations would prevent the construction of this reference plant.

**CDM** – Executive Board

page 24

#### STEP 2: Barrier analysis

#### Sub-step 2a: Identify barriers that would prevent the implementation of alternative scenarios

#### **Investment Barrier**

The main barrier to implement the project activity is the high investment that it requires. This barrier is especially important at this moment because of the World current financial situation. The lack of economic resources could cause delays or even cancellations in similar projects currently taking place in Brazil.

According to Marcos Sawaya Jank, Chairman of the Brazilian National Sugarcane Association (UNICA)<sup>2</sup>, although energy generation from sugarcane bagasse in Brazil has a great potential, there are several barriers that prevent the implementation of this kind of projects, such as:

- Depending on the location of the project and the geographical configuration of the grid, the cost of connexion is too high. The sugar / ethanol companies are responsible to undertake this expenditure.
- In 2008, investment and operating costs of energy cogeneration doubled respect 2007, due especially to the increase of costs of land, agricultural equipments, labour and steel.

Nowadays, investing in efficient equipments that generate extra electricity to export to the grid means an important extra cost to the project activity. According to the Ministry of Agriculture, the sugarcane industry prefers to invest in medium technologies that generate higher incomes and less expenditure in a short term<sup>3</sup>. Usually the revenues of selling electricity from a cogeneration project represent a small part of the total revenues of a sugar mill. Thus sugar mills tend to invest in their core business, sugar an ethanol, instead of investing in electricity generation for the grid.

#### Sub-step 2b: Eliminate alternative scenarios which are prevented by the identified barriers

As described above, there is only one alternative scenario that is not prevented by any barrier. The main alternative to the Project Activity is to continue the common practice in the sector and invest in medium technologies that generate less expenditure in a short term (Scenario 4).

The barriers identified in the development of the Project Activity undertaken without being registered as a CDM project activity are related to investment barriers. An investment analysis has been conducted in order to clearly assess the additionality of the project and to explain how the registration of the CDM Project Activity will alleviate the barriers that prevent the Project Activity from occurring in the absence of the CDM.

,

**CDM - Executive Board** 

page 25

#### STEP 3: Investment analysis

Given that the project has dual revenue streams, electricity for sale to the grid and certified emission reductions, and considering that one of the alternatives for power generation (P4 – The generation of power in the grid) is not under the control of project participants, the project proponent has selected benchmark analysis for investment analysis. An investment analysis of the project activity was conducted using the project Internal Return Rate (IRR) as financial indicator. Considering the fact that the project generates income, project IRR has been considered as appropriate financial indicator. IRR analysis has been prepared for a period of 20 years.

#### Benchmark analysis

A benchmark analysis has been considered as a suitable option for this project, and the project Internal Return Rate (IRR) has been considered as the financial indicator.

As it will be explained afterwards, the first real action of the project activity was the purchase of the turbine in 12/11/2007. Therefore, the investment analysis was also done in that period and Grupo Bertin used its own Weight Average Cost of Capital (WACC) to decide whether to carry out the project. The calculation of this benchmark is based on publicly available data sources.

According to the benchmark analysis, if the project IRR without CDM revenues is lower than the WACC, the project activity is not an interesting investment for the project participants.

#### Calculation and comparison of financial indicators

In order to follow the correct PDD chronology, project participants used as benchmark the value of the company's WACC on 2007, which is the minimum return rate expected by Grupo Bertin for its investments during this period.

The project's IRR (with and without CDM benefits) has been compared with the company's WACC. At the time of the investment decision, which is 2007, the benchmark of Grupo Bertin for this type of investment was 15.82% (the company's WACC, in terms of CDM, is more conservative than the SELIC<sup>4</sup> rate of 16.49%).

Regarding the IRR of the project activity and according to the "Guidance on the Assessment of Investment Analysis", included as an annex of the "Combined tool to identify the baseline scenario and demonstrate additionality", the investment analysis has been done in order to reflect the period of expected operation of the project activity. Thus, it has been considered a 20 years period, which is, in words of the manufacturer, the expected operational lifetime of the first boiler in perfect conditions.

In words of the "Guidance on the Assessment of Investment Analysis", input values used in all investment analysis should be valid and applicable at the time of the investment decision taken by the

-

<sup>&</sup>lt;sup>4</sup> Source: Banco Central do Brazil – Central Bank of Brazil (historic data of the interest rates fixed by the Copom and the SELIC Rate evolution) www.bcb.gov.br The SELIC is defined as the rate used as a reference in Brazil as risk free rate. This SELIC (16.49%) is the average from the last 3 years before the decision making. More information has been provided in the excel file for public consultation.

DM - Executive Board

page 26

project participant. The use of investment analysis to demonstrate additionality is intended to assess whether or not a reasonable investor would decide to proceed with a particular project activity without the benefits of the CDM. This decision will therefore be based on the relevant information available at the time of the investment decision and not information available at an earlier or later point.

Therefore, since the financial analysis was carried out in 2007, when the investment decision was taken, the estimations of power surplus available for sale that are considered in the financial analysis correspond to the more optimistic calculations taken from the engineering study that project owners ordered prior to the project implementation in order to ensure the technical feasibility of the project. This report was carried out by a Brazilian engineering company with 15 years of recognised experience in the sugarcane processing sector. According to the feasibility report, the sugarcane plant will achieve its top production of sugarcane (4,000,000 tones and 50.150 hectares) in 2017.

The estimations of sugarcane production and power generation from the engineering report used for discussing the project feasibility at the time of the investment decision will be shown to the DOE during the validation period.

The following main data<sup>5</sup> has been used in the financial analysis:

| Parameter                                  | Value                    |
|--|--------------------------|
| Total Investment (BRL)                     | 149,077,423 <sup>6</sup> |
| Electricity selling price (BRL/kWh - 2010) | 156 <sup>7</sup>         |
| Operational cost (BRL/year - 2010)         | 7,897,134 <sup>8</sup>   |

The São Fernando Biomass Cogeneration Project's cash flow shows that the IRR for the Project activity development, with and without CER revenues, is the following:

|                      | IRR    |
|----------------------|--------|
| With CER revenues    | 14.15% |
| Without CER revenues | 10.63% |

The result of the financial analysis shows that the IRR of the project activity without CER revenues is much lower than the company's benchmark. Therefore, as a conclusion of this financial analysis we can affirm that the project without the CDM incentive is not attractive for the company as a financial investment.

<sup>5</sup> The evidences are provided to the DOE

<sup>&</sup>lt;sup>6</sup> The file "Quadros de Usos e Fontes.xls" with the detailed inversion has been provided to the DOE. The cogeneration unit is designed to be built in two phases in order to follow the planting and maturing of cane sugar. Due to the seasonality of raw material and market demand, the company has a strategy of investing 54% of the total project in 2008 - 2009, leaving the second stage with 46% for 2012 - 2013.

<sup>&</sup>lt;sup>7</sup> A 15 year Power Purchase Agreement (PPA) starting at 2010, with a fix price of 156 R\$/MWh has been signed with the Brazilian Government through an energy public tender on August 2008.

<sup>&</sup>lt;sup>8</sup> Operations and General&Admin costs have been provided to the DOE. These costs come from: quantitative information concerning the salaries of employees, input costs, operational time...

<sup>&</sup>lt;sup>9</sup> The financial analysis has been provided to the validation team. All the values are referenced in the spreadsheet.

CDM – Executive Board

page 27

The IRR without CDM, and the sensibility analysis presented in the next section, demonstrates that unfortunately the project activity can not reach the benchmark but increases considerably the IRR of the project. The IRR calculated of the proposed activity (10.63%) is well below the benchmark (15.82%). The IRR calculations considering the CDM revenues (14.15%) is still below the benchmark, but further above than not considering the CDM even for the results of the sensitivity analysis. The financial analysis further confirmed the necessity of CDM application in order to carry on the project activity.

The extra revenues achieved by considering the CDM, makes the project return to increase, thus compensating the risks that project participants take with the project activity. Besides, CER revenues supposed an additional benefit when the decision was taken since they were supposed to be generated in stronger currencies (Euro) than the local currency.

Sao Fernando Açúcar e Álcool Ltda. belongs to a Brazilian holding company, Grupo Bertin, which includes several different activities in its pipeline such an energy generation, biodiesel, food companies, agro industry or infrastructures. Grupo Bertin has always been very concerned about the emissions related with its industrial activities. They have developed several GHG emission reduction projects such as reforestation, construction of a recycling plant for all the companies of the holding or wastewater treatments in the slaughterhouses and tanneries. In this way, Grupo Bertin thought that the CDM adds value to brand value of Grupo. When the financial analysis was presented to the Board of Grupo Bertin, they considered that, even the IRR was little below than the internal WACC (the benchmark) this CDM project activity was a strategic project to the Group in order to increase their commitment with the environment and, the Executive Board, agreed to develop the project.

The calculation of the company's WACC, the calculation of the SELIC and the full detailed cash flow spreadsheet has been presented to the DOE during the validation process.

#### Sensitivity analysis

According to the "Guidance on the Assessment of Investment Analysis", the ultimate objective of the sensitivity analysis is to determine the likelihood of the occurrence of a scenario other than the scenario presented, in order to provide a cross-check on the suitability of the assumptions used in the development of the investment analysis. Therefore, the parameters and the range of fluctuation of the sensitivity analysis have to be chosen considering realistic situations.

Although the electricity price is a meaningful parameter of the investment analysis, it can not been considered as parameter likely to fluctuate since the company has already signed a 15 year Power Purchase Agreement (PPA) starting at 2010, with a fix price of 156 R\$/MWh. The PPA of São Fernando plant has been signed with the Brazilian Government, through an energy public tender on August 2008, so there is no possibility of variation of the electricity price for the following 15 years. Any alternative financial scenario considering the fluctuation of the power price would not be realistic.

Thus, the sensitivity analysis was made by altering the parameters that are considered as likely to fluctuate over time. These are the following ones:

- Investments in Property, Plant and Equipment (PP&E).
- Operation Costs (Variable Cost).

**CDM - Executive Board** 

page 28

- General & Administrative Expenses.
- Energy output.

As per the "Guidance on the Assessment of Investment Analysis" recommendations, as a general point of departure variations in the sensitivity analysis should at least cover a range of  $\pm 10\%$ , unless this is not deemed appropriate in the context of the specific project circumstances.

Therefore, the sensitivity analysis was performed altering each parameter by a range realistically likely to happen and assessing the impact on the project IRR (without the CER revenues). The results are shown in the table below.

| PARAMETER                         | VARIATION | IRR    |
|-----------------------------------|-----------|--------|
|                                   | -10%      | 12.20% |
| Investments in PP&E               | 0         | 10.63% |
|                                   | +10%      | 9.24%  |
|                                   | -10%      | 11.00% |
| Operation Costs                   | 0         | 10.63% |
|                                   | +10%      | 10.26% |
|                                   | -10%      | 10.86% |
| General & Administrative Expenses | 0         | 10.63% |
|                                   | +10%      | 10.40% |
|                                   | -10%      | 8.27%  |
| Energy Output                     | 0         | 10.63% |
|                                   | +10%      | 12.79% |

As we can see, the IRR of the project activity without being registered as a CDM project is below the considered benchmark, even considering a hypothetical positive or negative variation of the main parameters within a range likely to happen.

The result of the sensitivity analysis makes evident that the project activity itself (without CDM revenues) is not financially attractive for the investor. Therefore, the most plausible baseline scenario for the project activity is given by the scenario #4 of the methodology.

#### STEP 4: Common practice analysis

Until July 1999, power exports from mills to the grid were legally not possible in Brazil and until 2000 they were inexistent, so the sugarcane processing industry developed low pressure, low efficiency 2-100 MWe units for self-supply only to ensure that excess bagasse would not accumulate and become a disposal problem. Almost all sugar mills and alcohol distilleries in Brazil employed small bagasse-fired steam turbine systems to provide just enough steam and electricity to meet the onsite factory needs. Most of these units date from about 20 years ago. Therefore, as a result of this situation, although most of the sugar and ethanol factories in Brazil currently consume their biomass residues, they do it in an inefficient manner, by using low efficient boilers and turbo-generators. Thus, there is usually no surplus electricity to sell. Actually, the first ethanol and sugar companies coming into the electricity market did not do it until recent years.

CDM – Executive Board

page 29

According to the Brazilian National Electricity Agency (ANEEL) power generation from sugarcane bagasse represents only 3.53%<sup>10</sup> of the total power generation installed capacity in Brazil, which means approximately 3,956 MW of 111,871 MW. Recent researches of the National Supply Company (CONAB) declare that setting up modern equipments, sugarcane industry would have a potential generation capacity up to 15,000 MW<sup>11</sup>. This means that around 11,000 MW from bagasse cogeneration are being wasted because of the use of inefficient equipments.

Despite the percentage of the total installed capacity that power generation from bagasse represents, the effective quantity of power exported from bagasse fired cogeneration units to the national grid (the National Interconnected System, SIN) is almost negligible. According to the National System Operator (ONS), the entity that coordinates the operation of the transmission and distribution units connected to the SIN, in 2008 only 178.1 GWh were injected to the grid from biomass fired power plants (not only bagasse fired, but the whole biomass fired for power generation), which means a 0.04% of the whole power generation of the national grid (448,802 GWh in 2008). The prior years this percentage was even lower, only 0.01% in 2007 and 0.006% in 2006<sup>12</sup>.

Regarding the thermoelectric generation in the national grid by type of fuel, in words of the ONS, in 2008 only 0.35% was from biomass (48.2% was from gas, 12.3% from coal and 27.4% nuclear power). These entire data make clear that, although power generation from bagasse is a common practice in the sugarcane industry, it is not common practice at all to export power from the sugarcane facilities to the Brazilian grid.

According to the Brazilian Ministry of Mines and Energy, bagasse fired power generation is currently addressed to meet the energy needs of the sugarcane processing plants, by using low efficiency thermal units. The technology commonly used consists of back-pressure cycles with low pressure and low efficiency boilers<sup>13</sup>.

In words of ANEEL, hydroelectricity accounts for approximately 70% of Brazilian installed capacity for electricity generation. As said before, the new 10-year Energy Plan 2008-17 of the Brazilian Government to avoid the dependence of water in electricity generation bets on an increasing use of fossil fuels. The plan created by de Ministry of Mines and Energy envisages the construction of 68 new power stations fired by coal, gas, diesel and oil by 2017, besides the 77 fossil fuel-based plants in operation. The Governmental Energy Plan until 2030 follows in the same steps as the 10-year plan, and foresees the increase of the fossil fuel fired power generation from the current 8% of the whole national energy up to  $18\%^{14}$ .

As it will be detailed afterwards, according to the National Supply Company (CONAB) the use of bagasse for power generation is almost limited to the sugarcane processing industry. Sugar and ethanol

<sup>&</sup>lt;sup>14</sup> Ministry of Mines and Energy, www.mme.gov.br/mme/menu/todas publicacoes.html

page 30

companies consume for cogeneration almost all their available bagasse (more than 89%). In terms of efficiency of power generation, the average of power generation per tonne of bagasse consumed barely exceeds 100 KWh/ton. This efficiency is even lower in the state of Mato Grosso do Sul<sup>15</sup>.

As shown in all these references and data, it is evident that sugarcane bagasse used as an energy source is not (and it will not be in the medium term) expressive in the national grid. Actually, the National Agroenergy Plan 2006-2011<sup>16</sup>, developed by the Ministry of Agriculture, foresees for 2020 a decreasing participation of the sugarcane bagasse cogeneration in the composition of the national grid and an increase of the gas generation.

Therefore, the proposed high efficiency electricity generation from sugarcane bagasse shall not be considered as a common practice in Brazil.

As said before, almost all the sugar and ethanol plants in Brazil generate electricity from their bagasse for self consumption. There are currently 413 registered sugarcane units in Brazil<sup>17</sup> and 270 of them generate electricity, according to the National Electricity Agency (ANEEL). But, in words of João Sampaio, Secretary of Agriculture of São Paulo, only few of them, around 10%, export electricity to the grid<sup>18</sup>. This means that only around 41 units generate extra energy and export it to the grid. There are 26 similar Brazilian projects registered in the CDM pipeline and another 27 projects at validation. Therefore, sugarcane bagasse cogeneration projects in Brazil without CDM are not a common practice<sup>19</sup>.

The Agroenergy Plan 2006-2011, developed by the Ministry of Agriculture<sup>20</sup>, foresees a great increase of the Brazilian sugarcane industry during the following years. According to this report, in 2020 the industry could achieve a potential cogeneration between 16 and 21 GW per year. However, the economically feasible potential is less than 65% of this forecast, and it is concentrated in a few plants. Due to the current policy of investments of the sugarcane companies, which usually adopt low efficient technological solutions, the potential cogeneration of the industry will achieve in 2010 only around 0.5 and 2 GW. Considering the expansion of the sugarcane production, if technologically more advanced solutions were implemented in the sector, the economically feasible cogeneration could reach until 3.8 GW in 2010.

page 31

According to a recent sectoral report<sup>21</sup> of the CONAB in cooperation with the Ministry of Agriculture, none of the sugar and alcohol production plants located in the state of Mato Grosso do Sul currently export electricity to the national grid.

In terms of efficiency, the table below shows how the sugarcane bagasse is used in each state of the south and central areas of Brazil.

|                     | Sugarcane production (thousand tonnes) | % of bagasse used for cogeneration | Power generation<br>per tonne of bagasse<br>(KWh/ton) | Power generation<br>per tonne of milled sugarcane<br>(KWh/ton) |
|---------------------|--|------------------------------------|---|--|
| São Paulo           | 78,979                                 | 90.8%                              | 91.3  | 23.04  |
| Paraná              | 10,774                                 | 92.2%                              | 121.5   | 27.77  |
| Minas Gerais        | 10,090                                 | 76.7%                              | 155.6   | 31.01  |

| Central-South Areas | 106,272                                | 88.84%                             | 99.9  | 24.35  |

Using of bagasse- Source: CONAB, April 2008. <a href="https://www.conab.gov.br/conabweb/download/safra/perfil.pdf">www.conab.gov.br/conabweb/download/safra/perfil.pdf</a>

As shown in the table, sugar and ethanol plants in Mato Grosso do Sul have the lowest efficiency of power generation (69.4 KWh per tonne of bagasse consumed, which means 2.68% efficiency, considering the NCV of the bagasse used in the project plant). In other states like Minas Gerais, the most efficient one, sugarcane plants generate electricity per tonne of bagasse in average more than twice as much as Mato Grosso do Sul. Plants from Mato Grosso do Sul also have the lowest percentage of bagasse used for cogeneration, which means that these plants barely generate electricity for self consume and they do it in a very inefficient way. Therefore, these data make evident that the use of high efficiency equipments for electricity generation from sugarcane bagasse is not a common practice in the state.

On the other hand, according to the project participants' data, when São Fernando achieves its top generation capacity the plant will generate around 468 KWh per tonne of bagasse consumed, which means 18.07% of efficiency. This means that, thanks to the high efficiency equipments installed in the cogeneration unit, the plant will generate with the same bagasse consumption more than six times as much power as the currently existing plants in Mato Grosso do Sul.

Besides, all the bagasse generated in the São Fernando's sugarcane production process will be used for power generation.

As a conclusion, we can affirm that generating electricity for exporting to de grid is not a common practice in the sugarcane industry of Brazil, but even less common in the state of Mato Grosso do Sul.

The proposed increase of energy efficiency considers a technology that is not commonly used by the sector. More efforts will be necessary to train operators and adapt the processes. More quality control of the bagasse will be necessary and studies on the supply chain will be necessary. The use of low efficient

\_

page 32

power plant is common practice in the region and sector, but there are some other sugarcane plants planning to invest in a high efficient power and heat plant. Those plants are considering the CDM revenues and they have the Projects in a validation status (i.e. "Angélica Cogeneration Project (mill Angélica) – an Adecoagro Project Activity" and "LDC cogeneration project at Rio Brilhante Mill", both of them located in Mato Grosso do Sul). The operational conditions of the proposed CDM projects at validation or registered under the ACM0006 have been extracted from the UNFCCC. The following table demonstrates all the data of the operational conditions of those Projects and demonstrates that Sao Fernando and "Cosan – Bonfim Biomass Residue Cogeneration Project" are the only projects that considered installing a 100 bar boiler:

| ACM0006  | Status (01/07/2010) |         | 0)           |
|----------|---------------------|---------|--------------|
| Pressure | Registered          | At Val. | <b>Total</b> |
| ?        |                     | 1       | 1            |
| 42       |                     | 2       | 2            |

#### **B.6.** Emission reductions:

# **B.6.1.** Explanation of methodological choices:

The project activity mainly reduces  $CO_2$  emissions through substitution of power and heat generation with fossil fuels by energy generation with biomass residues. The emission reduction,  $ER_y$ , carried out by the project activity during a given year y is the difference between the emission reductions through substitution of electricity generation with fossil fuels ( $ER_{electricity,y}$ ), the emission reductions through substitution of heat generation with fossil fuels ( $ER_{heat,y}$ ), project emissions ( $PE_y$ ), emissions due to leakage ( $L_y$ ) and, where this emission source is included in the project boundary and relevant, baseline emissions due to the natural decay or burning of anthropogenic sources of biomass residues ( $ER_{biomass,y}$ ), as follows:

$$ER_v = ER_{heat.v} + ER_{electricity.v} + BE_{biomass.v} - PE_v - L_v$$

Where:

 $ER_y$  = Emission reductions of the project activity during the year y (tCO<sub>2</sub>/yr).

#### **CDM - Executive Board**

page 33

 $ER_{electricity,y}$  = Emission reductions due to displacement of electricity during the year y

 $(tCO_2/yr)$ .

 $ER_{heat,y}$  = Emission reductions due to displacement of heat during the year y (tCO<sub>2</sub>/yr) = Baseline emissions due to natural decay or burning of anthropogenic sources

of biomass residues during the year y (tCO<sub>2</sub>e/yr).

PE<sub>y</sub> = Project emissions during the year y (tCO<sub>2</sub>/yr). L<sub>y</sub> = Leakage emissions during the year y (tCO<sub>2</sub>/yr).

#### Emission reductions due to displacement of heat, ERheat, v

The emission reductions due to displacement of heat are assumed as zero ( $ER_{heat,y} = 0$ ) because the thermal efficiency in the project plant is similar compared with the thermal efficiency of the reference plant considered in the baseline scenario.

#### Project emissions, PE<sub>v</sub>

Project emissions include:

- CO<sub>2</sub> emissions from transportation of biomass residues to the project site (PET<sub>y</sub>).
- CO<sub>2</sub> emissions from on-site consumption of fossil fuels due to the project activity (PEFF<sub>v</sub>).
- CO<sub>2</sub> emissions from consumption of electricity (PE<sub>FC v</sub>).

Project emissions are calculated as follows:

$$PE_v = PET_v + PEFF_v + PE_{ECv} + GWP_{CH4} \cdot \left(PE_{Biomass CH4, v} + PE_{ww CH4, v}\right)$$

Where:

 $PET_v$  =  $CO_2$  emissions during the year y due to transport of the biomass residues to the project

plant ( $tCO_2/yr$ ).

PEFF<sub>v</sub> =  $CO_2$  emissions during the year y due to fossil fuels co-fired by the generation facility

or other fossil fuel consumption at the project site that is attributable to the project

activity (tCO<sub>2</sub>/yr).

 $PE_{EC,v}$  =  $CO_2$  emissions during the year y due to electricity consumption at the project site that

is attributable to the project activity (tCO<sub>2</sub>/yr).

GWP<sub>CH4</sub> = Global Warming Potential for methane valid for the relevant commitment period.

 $PE_{BiomassCH4, y}$  = CH<sub>4</sub> emissions from the combustion of biomass residues during the year y (tCH<sub>4</sub>/yr).

PE<sub>WW,CH4,y</sub> = CH<sub>4</sub> emissions from wastewater generated from the treatment of biomass residues in

year y (tCH<sub>4</sub>/yr).

There are no emissions due to transport of the biomass to the plant during the project activity, so  $PET_y = 0$ . There will be no on-site consumption of fossils fuels during the project activities, therefore  $PEFF_y = 0$ . The electricity demand of the projected plant will be satisfied with the bagasse electricity generation, therefore,  $PE_{EC,y} = 0$ .

UNFCCC

**CDM – Executive Board** 

page 34

Emissions from the combustion of biomass residues and from wastewater generated from the treatment of biomass are excluded.

# Baseline emissions due to natural decay or burning of anthropogenic sources of biomass residues, $BE_{biomass,y}$

Baseline emissions due to uncontrolled burning or decay of the biomass residues are zero ( $BE_{biomass,y} = 0$ ), since the biomass residues would not decay or be burnt in the absence of the project activity.

#### Leakage emissions, L<sub>v</sub>

Where the most likely baseline scenario is the use of the biomass residues for energy generation (as in scenario 4), the diversion of biomass residues to the project activity is already considered in the calculation of baseline reductions. In this case, leakage effects do not need to be addressed, therefore  $L_y$ = 0.

#### Emission reductions due to displacement of electricity, ER<sub>electricity</sub>, v

Emission reductions due to the displacement of electricity are relevant for scenario 4 and are calculated by multiplying the net quantity of increased electricity generated with biomass residues as a result of the project activity  $(EG_y)$  with the  $CO_2$  baseline emission factor for the electricity displaced due to the project  $(EF_{electricity,y})$ , as follows:

$$ER_{electricity, y} = EG_y \cdot EF_{electricity, y}$$

Where:

 $ER_{electricity, y}$  = Emission reductions due to displacement of electricity during the year y (tCO<sub>2</sub>/yr).

EG<sub>v</sub> = Net quantity of increased electricity generation as a result of the project activity

(incremental to baseline generation) during the year y (MWh).

 $EF_{electricity,y}$  =  $CO_2$  emission factor for the electricity displaced due to the project activity during the

year y (tCO<sub>2</sub>/MWh).

The project activity displaces electricity from other grid-connected sources.

The emission factor for displacement of electricity ( $EF_{electricity,y}$ ) corresponds to the grid emission factor ( $EF_{electricity,y} = EF_{grid,y}$ ), and its calculation is done following the procedures established by the "*Tool to calculate the emission factor for an electricity system*"; version 01.1. The  $EF_{grid,y}$  is determined in section B.6.3.

EG<sub>y</sub> is determined as the difference between the electricity generation in the project plant and the quantity of electricity that would be generated by other power plant(s) using the same quantity of biomass residues that is fired in the project plant, as follows:

$$EG_y = EG_{project\ plant,y} - \varepsilon_{el,other\ plant(s)} \cdot \frac{1}{3.6} \sum BF_{k,y} NCV_k$$

UNFCCC

#### **CDM - Executive Board**

page 35

Where:

EG<sub>y</sub> = Net quantity of increased electricity generation as a result of the project activity

(incremental to baseline generation) during the year y (MWh).

 $EG_{project plant,y}$  = Net quantity of electricity generated in the project plant during the year y (MWh).

 $\varepsilon_{\text{el, other plant(s)}}$  = Average net energy efficiency of electricity generation in (the) other power plant(s) that would use the biomass residues fired in the project plant in the absence of the

project activity (MWh<sub>el</sub>/MWh<sub>biomass</sub>).

 $BF_{k,y}$  = Quantity of biomass residue type k combusted in the project plant during the year y

(tons of dry matter or litre).

 $NCV_k$  = Net calorific value of the biomass residue type k (GJ/ton of dry matter or GJ/litre).

Therefore:  $ER_y = ER_{electricity, y}$ 

## B.6.2. Data and parameters that are available at validation:

| Data / Parameter:           | ε <sub>el,reference plant</sub>  |

| Any comment:                | Applicable to scenario 4.  |

#### **B.6.3.** Ex-ante calculation of emission reductions:

As described in B.6.1, emission reductions of the project activity in a given year y are:

$$ER_{y} = ER_{electricity,y} = EG_{y} \cdot EF_{electricity,y}$$

The emission factor for the displacement of electricity ( $EF_{electricity,y}$ ) corresponds to the Brazilian grid emission factor ( $EF_{gridy,y}$ ). The value of the grid emission factor has been taken from the data of the

UNFCCC

**CDM - Executive Board** 

page 36

Brazilian DNA<sup>22</sup>, which has used "Tool to calculate the emission factor for an electricity system" in order to calculate it.

## STEP 1. Identify the relevant electric power system

For the purpose of determining the electricity emission factors, a **project electricity system** is defined by the spatial extent of the power plants that are physically connected through transmission and distribution lines to the project activity (e.g. the renewable power plant location or the consumers where electricity is being saved) and that can be dispatched without significant transmission constraints.

In June of 2008, the Brazilian DNA published in the Official Journal a Resolution<sup>23</sup> which adopts a unique electricity system for CDM projects. This is known as *Sistema Interligado Nacional* (SIN), the National Interconnected System.

# STEP 2. Select an operating margin (OM) method

The calculation of the operating margin emission factor  $(EF_{grid,OM,y})$  is based on one of the following methods:

- (a) Simple OM, or
- (b) Simple adjusted OM, or
- (c) Dispatch data analysis OM, or
- (d) Average OM.

As the responsible for calculating the OM emission factor in Brazil, the Brazilian DNA uses the Dispatch data analysis OM method. For this method it is necessary to use the year in which the project activity displaces grid electricity and to update the emission factor annually during monitoring.

#### STEP 3. Calculate the operating margin emission factor according to the selected method

The dispatch data analysis OM emission factor ( $EF_{grid,OM-DD,y}$ ) is determined based on the power units that are dispatched at the margin during each hour h where the project is displacing electricity. This approach is not applicable to historical data and, thus, requires annual monitoring of  $EF_{grid,OM-DD,y}$ .

The emission factor is calculated as follows:

$$EF_{grid,OM-DD,y} = \frac{\sum EG_{PJ,h} \cdot EF_{EL,DD,h}}{EG_{PJ,y}}$$

<sup>&</sup>lt;sup>22</sup> Ministry of Science and Technology. <a href="www.mct.gov.br/index.php/content/view/74689.html">www.mct.gov.br/index.php/content/view/74689.html</a>

<sup>&</sup>lt;sup>23</sup> Ministry of Science and Technology, www.mct.gov.br/index.php/content/view/14797.html

#### **CDM - Executive Board**

page 37

Where:

 $EF_{grid,OM-DD,y}$  = Dispatch data analysis operating margin CO<sub>2</sub> emission factor in year y (tCO<sub>2</sub>/MWh).

 $EG_{PLh}$  = Electricity displaced by the project activity in month m of year y (MWh).

 $EF_{EL,DD,h}$  = CO<sub>2</sub> emission factor for power units in the top of the dispatch order in month m in year

y (tCO<sub>2</sub>/MWh).

 $EG_{PJ,y}$  = Total electricity displaced by the project activity in year y (MWh).

m = Months in year y in which the project activity is displacing grid electricity.

y = Year in which the project activity is displacing grid electricity.

The  $EF_{EL,DD,h}$ ,  $EF_{EL,DD,m}$  and  $EF_{EL,DD,m}$  are displayed on the Brazilian DNA website<sup>24</sup> for the every year, but only the  $EF_{EL,DD,m}$  will be used in order to calculate the emission reductions.

According to the DNA data,  $EF_{grid,OM-DD,2008}$  for the first crediting period is:

 $EF_{\textit{grid},OM\text{-}DD,2008} = 0.4766 \ tCO_2/MWh.$ 

#### STEP 4. Identify the cohort of power units to be included in the build margin

The build margin is also calculated by the Brazilian DNA.

In terms of vintage of data, project participants can choose between one of the following two options:

Option 1. For the first crediting period, calculate the build margin emission factor ex-ante based on the most recent information available on units already built for sample group m at the time of CDM-PDD submission to the DOE for validation. For the second crediting period, the build margin emission factor should be updated based on the most recent information available on units already built at the time of submission of the request for renewal of the crediting period to the DOE. For the third crediting period, the build margin emission factor calculated for the second crediting period should be used. This option does not require monitoring the emission factor during the crediting period.

Option 2. For the first crediting period, the build margin emission factor shall be updated annually, expost, including those units built up to the year of registration of the project activity or, if information up to the year of registration is not yet available, including those units built up to the latest year for which information is available. For the second crediting period, the build margin emissions factor shall be calculated ex-ante, as described in option 1 above. For the third crediting period, the build margin emission factor calculated for the second crediting period should be used.

The option 2 has been chosen for the project activity.

<sup>&</sup>lt;sup>24</sup> Ministry of Science and Technology, www.mct.gov.br/index.php/content/view/303077.html#ancora

**CDM – Executive Board** 

page 38

#### STEP 5. Calculate the build margin emission factor

The build margin emissions factor is the generation-weighted average emission factor (tCO<sub>2</sub>/MWh) of all power units m during the most recent year y for which power generation data is available, calculated as follows:

$$EF_{grid,BM,y} = \frac{\sum_{m} EG_{m,y} \times EF_{EL,m,y}}{\sum_{m} EG_{m,y}}$$

Where:

 $\mathrm{EF}_{grid,BM,y}$ = Build margin  $CO_2$  emission factor in year y ( $tCO_2/MWh$ ).

= Net quantity of electricity generated and delivered to the grid by power unit m in year y  $EG_{m,v}$ 

(MWh).

=  $CO_2$  emission factor of power unit *m* in year *y* (t $CO_2$ /MWh).  $\mathrm{EF}_{\mathit{ELm},y}$ 

= Power units included in the build margin.

= Most recent historical year for which power generation data is available. y

According to the DNA data,  $EF_{grid,BM,2008}$  for the first crediting period is:

$$EF_{grid,BM,2008} = 0.1458 \text{ tCO}_2/\text{MWh}.$$

#### STEP 6. Calculate the combined margin emissions factor

The combined margin emissions factor is calculated as follows:

$$EF_{grid,CM,y} = EF_{grid,OM,y} \times w_{OM} + EF_{grid,BM,y} \times w_{BM}$$

Where:

 $EF_{grid,BM,y}$ = Build margin  $CO_2$  emission factor in year y (t $CO_2$ /MWh). = Operating margin CO<sub>2</sub> emission factor in year y (tCO<sub>2</sub>/MWh).

 $\mathrm{EF}_{grid,OM,y}$ 

= Weighting of operating margin emissions factor (%).  $w_{\text{OM}}$ = Weighting of build margin emissions factor (%).  $W_{BM}$ 

In this case, the default weights are 50%. Therefore, according to Brazilian DNA data, the combined margin emissions factor for the first crediting period is:

$$EF_{2008} = EF_{grid,CM,2008} = 0.4766 \times 0.5 + 0.1458 \times 0.5 = 0.3112(tCO_2 / MWh)$$

**CDM - Executive Board** 

page 39

Therefore, the estimated emission reductions for the first crediting period are the following:

| Year              | Net quantity of<br>electricity<br>generated in the<br>project plant<br>(MWh) | Quantity of bagasse combusted in the project plant | Ex-ante<br>Emission Factor<br>(tCO2e/MWh) | Estimation of overall Emission Reduction (tCO <sub>2</sub> ) |
|-------------------|--|--|---|--|
| 06/2011 - 12/2011 | 180,173  | 414,773  | 0.3112                                    | 47,110   |
| 2012              | 364,336  | 802,993  | 0.3112                                    | 96,035   |
| 2013              | 458,143  | 978,980  | 0.3112                                    | 121,426  |
| 2014              | 458,143  | 978,980  | 0.3112                                    | 121,426  |
| 2015              | 458,143  | 978,980  | 0.3112                                    | 121,426  |
| 2016              | 458,143  | 978,980  | 0.3112                                    | 121,426  |
| 2017              | 458,143  | 978,980  | 0.3112                                    | 121,426  |
| 01/2018 - 05/2018 | 69,768   | 149,083  | 0.3112                                    | 18,491   |

The ex-ante calculations of the emission reductions in the PDD differ from the ones considered in the Financial Analysis due to the following reasons:

- The Financial Analysis presented in the PDD was the carried out at the time of decision making, thus in 2007.
- · At that time, Grupo Bertin planned the plantation according to the expected availability in time of the surface for the sugar cane plantation. The Financial Analysis was carried out according to this surface availability and according to the results of the feasibility study.

In 2009, since the land was available earlier than expected, Sao Fernando decided to accelerate the process of planting and thus the implementation of the project. With the aim of accurately determine the baseline scenario, the ex-ante calculations of the emission reduction have been assessed based on the situation assessed in 2009 hence considering the acceleration of the planting process.

#### **B.6.4** Summary of the ex-ante estimation of emission reductions:

| the purpose of calculating |  |
| expected emission          |  |
| reductions in section B.5  |  |
| Description of             | Measurements will be carried out at internal laboratory of Usina São                                 |
| measurement methods and    | Fernando and according to relevant international standards. The measure of                           |
| procedures to be applied:  | the NCV will be based on dry biomass.  |
|                            | Analysis will be done at least every six months, taking at least three samples for each measurement. |
|                            | Data will be kept for the later of, two years after the end of the crediting                         |
|                            | period or the last issuance of CERs for the project activity.  |
| QA/QC procedures to be     | Since there are no NCV measurements from previous years, the consistency                             |
| applied:                   | of the measurements will be checked by comparing the measurement results                             |
|                            | with default values by the IPCC.   |
| Any comment:               |  |

# **B.7.2.** Description of the monitoring plan:

For the monitoring plan, the following structure will be established:

The following parameters will be monitored:

#### CDM – Executive Board

page 44

#### 1. Electricity generated in the project plant.

This data will be measured through electricity meters. The measure of the power exported to the grid will be done according to standards and monitoring patterns of the CCEE (*Câmara de Comercialização de Energia Elétrica*, a governmental institution linked to ANEEL, *Agência Nacional de Energia Elétrica*).

The consistency of metered net electricity generation will be cross-checked with receipts from the electricity sales. However, it must be taken into account that there will be sale receipts only for the power exported to the grid, not for the whole power generation of the plant.

In order to ensure data consistency, the readings of the devices will be recorded in an electronic spreadsheet and the invoices of electricity sales will be archived.

#### 2. Quantity of combusted bagasse in the project plant.

As per common practice in the sugarcane sector, the measurement of the quantity of bagasse combusted in the project activity is done in an indirect way. The total bagasse consumed in the facility is based on the total sugarcane crushed and the percent amount of bagasse in the sugarcane. The percentage of bagasse per unit of cane is measured in the plant's internal laboratory.

Trucks carrying the sugarcane will be weighted (loaded and empty) in a weight bridge located at the entrance of the plant. Samples of the sugarcane carried by each truck will be analyzed and the percentage of fiber in the cane will be calculated. The quantity of fiber in a specific amount of sugarcane is the same as in the bagasse proceeding from it; therefore, the quantity of bagasse available for cogeneration is directly proportional to the sugarcane produced. Data will be adjusted for the moisture content in order to determine the quantity of dry biomass. The quantity will be crosschecked with the quantity of electricity (and heat) generated.

The quantity of bagasse combusted in the project plant is based on the quantity of heat generated in each boiler. The performance guarantee of the boilers establishes the exact proportion between the bagasse consumed and the heat generated. Heat generation is continuously monitored in both boilers.

Data will be recorded on a working day basis by the Technical department and archived in electronic spreadsheets. It will also be prepared annually an energy balance for all the installed boilers, based on stock changes.

The whole bagasse production of the sugarcane plant will be used for power generation. Only a small percentage of each crop is stocked for restarting the cogeneration unit after the intercrop period.

# 3. Moisture content of bagasse (in order to determine the quantity of biomass residue in dry matter).

Moisture content of the biomass residue will be continuously monitored. Mean values will be calculated at least annually. Samples will be determined by the plant's own qualified laboratory, which follows the procedures of the Center of Sugarcane Technology (CTC, *Centro de Tecnologia Canavieira*).

CDM – Executive Board

page 45

4. Net caloric value of bagasse (in order to determine NCV of biomass residue).

The net caloric value of the bagasse will be analyzed according to the relevant national standards, and measured by the plant's own qualified laboratory. As per the methodology specifications, analysis will be done at least every six months, taking at least three samples for each measurement.

The procedures for calibration and maintenance of the instruments will be done according to the regulations of Associação Brasileira de Normas Técnicas (ABNT), and Instituto Nacional de Metrologia, Normalização e Qualidade Industrial (INMETRO), and will be done during preventive maintenance operation of Usina São Fernando.

The São Fernando plant will organise the staff training in the appropriate monitoring, measurement and reporting techniques. The responsible for the cogeneration unit of the plant will also be the person in charge for organising the staff training.

In order to ensure the correct development of the monitoring, the plant has implemented the following documents of procedures:

- CDM Responsible Procedure: it appoints a responsible for the monitoring and explains which his duties and obligations are.
- Formation for Monitoring Procedure: it resumes the procedures that must be taken into account in order to achieve a proper training for the staff that is in charge for the monitoring.

Both documents will be shown to the DOE during the validation period.

B.8. Date of completion of the application of the baseline study and monitoring methodology and the name of the responsible person(s)/entity(ies):

Date of completion of the current version of baseline study and monitoring methodology: 24/08/2009

The name and contact data of the responsible person/entity are:

page 47

#### **SECTION D.** Environmental impacts

# **D.1.** Documentation on the analysis of the environmental impacts, including transboundary impacts:

The Secretary of Environment of the State of Mato Grosso do Sul (SEMAC) is responsible for analyzing any possible environmental impact due to the project activity normal development. The licenses required by the Brazilian environmental regulation are:

- The preliminary license (*Licença Prévia, LP*).
- The construction license (*Licença de Instalação*, *LI*).
- The operating license (*Licença de Operação, LO*).

The project plant has all the licenses required by the Brazilian environmental regulation, with the following numbers:

- Preliminary licenses number 20/2009 (for the transmission line) and 27/2009 (for the substation).
- Construction license number 129/2008.
- Operating licenses protocol number 256/2009 (for the cogeneration unit), 285/2009 (for the substation) and 288/2009 (for the transmission line).

The power plant also has its authorization and registration on the National Agency of Electrical Energy (ANEEL) to operate as an independent power producer.

No transboundary impacts resulting from this project activity are expected. All the relevant impacts occur within Brazilian borders and have been mitigated to comply with the environmental requirements for project's implementation.

D.2. If environmental impacts are considered significant by the project participants or the <u>host</u> <u>Party</u>, please provide conclusions and all references to support documentation of an environmental impact assessment undertaken in accordance with the procedures as required by the host Party:

Not applicable. The project activity expects no significant environmental impacts.

**CDM - Executive Board** 

page 48

## **SECTION E.** Stakeholders' comments

#### E.1. Brief description how comments by local stakeholders have been invited and compiled:

According to Brazilian legislation, in order to obtain all the licenses for operating the plant, the project must go into public discussion with local stakeholders. It is also mandatory the announcement of the issuance of the licenses in the Official Journal (*Diário Oficial da União*) and in regional newspapers (*Diário MS*) to ensure that the process is public and allows for public comments.

Regarding the CDM activity, to get the letter of approval from the Brazilian DNA it is also required the invitation of selected stakeholders to comment the project design document that is sent to validation. The project developers sent a cover letter to the stakeholders, in order to introduce themselves and the project activity. This cover letter will be available for the DOE during the validation process.

The organizations and entities invited to comment on the project were:

| Entity   | Website                      |
|--|------------------------------|
| Dourados City Council  | www.dourados.ms.gov.br       |
| Dourados Municipal Chamber   | www.camaradourados.ms.gov.br |

| UDOP – Bioenergy Producers Association                                     | www.udop.com.br              |
| UNICA - Sugarcane Industry Association                                     | www.unica.com.br             |
| CTC – Sugarcane Technology Centre  | www.ctc.com.br               |
| Brazilian Forum of NGOs and Social Movements for Environment and           | www.fboms.org.br             |
| Development – FOBMS  |                              |
|  |                              |

Since the municipality of Dourados does not have any Environmental Secretary or other relevant local environmental institution, project participants decided to invite to comment on the project activity to the City Council and the two main environmental institutions of the state of Mato Grosso do Sul, which are SEMAC and IMASUL.

UNFCCC

**CDM - Executive Board** 

page 49

### **E.2.** Summary of the comments received:

The Sugarcane Technology Centre (CTC) asked for more information about the CDM projects carried out by sugarcane processing companies that are associated to this institution.

# E.3. Report on how due account was taken of any comments received:

In order to solve the comments received from the Sugarcane Technology Centre (CTC), a Project Idea Note (PIN) of the São Fernando Cogeneration Project was sent to them. The PIN extended the information about the project contained in the first stakeholders' notification. The project developers also informed to the institution that the full version of the Project Design Document was available for public comments at the UNFCCC website until 23 May 2009. The stakeholder also received a copy of the first version of the PDD translated into Portuguese and the report of the project activity's contribution under the Clean Development Mechanism towards sustainable development, as per Annex III of Resolution no. 1 of the Brazilian DNA.

The stakeholder's request of information, the project developers' reply, the PIN sent to the Sugarcane Technology Centre, the Portuguese version of the PDD and the report of the project activity's contribution towards sustainable development will be available for the DOE during the validation period.
